

Implement Client Script & UI Policy (Incident)

1. Ideation Phase

ServiceNow Incident Management

Detailed Phase Report

1. Ideation Phase

1.1 Introduction

The project Implement Client Script & UI Policy (Incident) is a ServiceNow-based project focused on improving the Incident Management form. ServiceNow Incident Management is used to record, track and resolve issues reported by users. An Incident form contains many fields and the information entered into those fields should follow the organization's requirements.

The main idea of this project is to make the Incident form more intelligent and user-friendly. Instead of showing the same behavior for every situation, the form can respond to user actions. A Client Script can execute client-side JavaScript, while a UI Policy can dynamically control field properties such as mandatory, visible and read-only.

1.2 Problem Identification

In a normal Incident form, users may not always know which information is required for a particular situation. This can lead to incomplete records, unnecessary data entry or inconsistent information. For example, a field may be important only when a particular value is selected in another field.

If every field is made mandatory all the time, the form can become difficult to use. If no validation or dynamic behavior is provided, important information may be missed. Therefore, a conditional form behavior is useful.

1.3 Proposed Idea

The proposed solution is to configure the Incident form using two ServiceNow features. First, a Client Script will be used where programmable client-side logic is required. Second, a UI Policy will be used to control field behavior based on a condition.

The user interacts with the Incident form, ServiceNow evaluates the configured condition and the required field behavior is applied. This makes the data-entry process more controlled without changing the overall purpose of the Incident table.

1.4 Objectives

The major objectives are:

- Improve the usability of the Incident form.
- Implement dynamic client-side behavior using Client Script.
- Control field properties using UI Policy and UI Policy Actions.
- Reduce incomplete or inconsistent Incident information.
- Test both triggering and non-triggering conditions.
- Document the configuration clearly.
- Demonstrate the final working result in ServiceNow.

1.5 Scope of the Project

The project is limited to client-side behavior on the ServiceNow Incident form. It covers the creation and testing of the required Client Script and UI Policy. It does not attempt to replace the complete Incident Management process, server-side business rules or database design.

The exact field and condition used should follow the project instruction supplied by the instructor.

1.6 Expected Outcome

At the end of the project, the Incident form should respond according to the configured requirement. The selected condition should trigger the intended Client Script or UI Policy behavior, and the user should be guided to enter the required Incident information.

1.7 Conclusion

The Ideation Phase establishes the reason for the project, the problem being addressed, the proposed solution and the expected result. The next phase converts this idea into clear functional and non-functional requirements.
