

Implement Client Script & UI Policy (Incident)

2. Requirement Analysis

ServiceNow Incident Management

Detailed Phase Report

2. Requirement Analysis

2.1 Introduction

Requirement Analysis identifies exactly what the Incident project must do. It converts the project idea into a list of functions, inputs, outputs, conditions and testing expectations. This phase is important because incorrect requirements can lead to incorrect Client Script or UI Policy configuration.

2.2 Functional Requirements

The system shall:

1. Allow an authorized user to open the Incident form.
2. Allow the user to create or edit an Incident record.
3. Detect the configured field value or form event.
4. Execute the Client Script for its configured event.
5. Evaluate the UI Policy condition.
6. Apply the required UI Policy Actions.
7. Make the configured field mandatory, visible or read-only when required.
8. Allow the Incident to be submitted after all required information is provided.
9. Preserve normal behavior when the triggering condition is not satisfied.

2.3 Non-Functional Requirements

- Usability: The Incident form should be simple and understandable.
- Performance: Client-side actions should occur without unnecessary delay.
- Maintainability: Configuration should be easy to understand and update.
- Reliability: The rule should behave consistently for repeated tests.
- Security: Only users with the required ServiceNow permissions should modify configuration.

2.4 Inputs

The inputs are values entered or changed on the Incident form. Possible fields include Category, Subcategory, Impact, Urgency, Priority, Short Description and Description. The exact triggering field must be selected according to the assigned project requirement.

2.5 Processing

When the user interacts with the form, the configured client-side logic is evaluated. A Client Script can read the relevant value and perform an action. A UI Policy checks its condition and applies its UI Policy Actions. The processing takes place on the form before the Incident record is finally submitted.

2.6 Outputs

The output is the updated behavior of the Incident form. Depending on the requirement, a field may become mandatory, visible, hidden, read-only or editable. The final Incident record should contain all information required by the configured rule.

2.7 Requirement Traceability

Requirement → Configuration → Test.

Dynamic logic requirement → Client Script → Client Script test case.

Field state requirement → UI Policy → UI Policy Action test case.

Valid submission requirement → Incident submission test.

This traceability makes it easier to confirm that every requirement has been implemented and tested.

2.8 Conclusion

Requirement Analysis provides the exact basis for the design. Once the required fields, conditions and expected outputs are identified, the project can move to the Project Design Phase.
